Statistical inference of transcriptomics data
Part II: comparing methods

Simone Tiberi

Department of Statistical Sciences
The University of Bologna

Comparing methods

- Methods validation often done in multiple steps.
- Simulations:
  - pro - ground truth known;
  - pro - simulate diverse scenarios: robustness/sensitivity analyses (vary number of samples, cells, sparsity data, strength of difference we aim to detect, etc...);
  - cons - only partially realistic: real data generation process usually more complex (biology + measurement).
- Real data analyses:
  - pro - realistic;
  - cons - lack of ground truth: build it in lab (expensive, and limited: only for a few genes; not always possible), or lists of "reasonable results" (based on current biological knowledge): e.g., `https://www.proteinatlas.org/search/wound+healing`.

Comparing methods

- Semi-simulated datasets (more realistic simulations):
  - generate a simulation, using real data as anchor;
  - parametric: estimate model parameters from real data -> use them to generate simulations;
  - non-parametric: real data measurements -> re-arrange them.

Assessing a method's performance

- Method comparisons based on simulations where we know the ground truth.
- Main plots:
  - **ROC**: true positive rate (TPR) vs false positive rate (FPR); Diagonal line = the blind/random model;
  - **FDR**: TPR vs FDR (more interesting than the ROC in this field) - check if FDR is really controlled;
  - **FPs** vs top significant genes: focus on the very top genes.
- In both ROC and FDR plots, focus on the left area - top selected genes.

FPs vs top selected genes

Venn diagram

- Even without a ground truth, it shows similarities among methods.
- Set a cutoff and compare significant results for each method.

What comes after RNA-seq studies?

- The main aim of RNA-seq studies is to identify genes/transcripts/pathways which show interesting characteristics (DGE, DAS, ORA, etc...): these genes will typically be studied more in depth in further biological analyses.
- This is why we care about top (most significant) results: we often select a few (very) significant results that undergo further studies.
